## 5 Conclusion

# Context: Multi-Layer Graphs

**A multilayer graph** is a collection of interconnected graphs that share a common set of vertices while featuring distinct sets of edges.

⇒ inherent representation for **multi-model data**.

Figure 1: A multi-layer graph representing AUCS social network interactions.

## A conventional clustering algorithm :

- Identifies  $k$  clusters in a **single-layer graph**.
- Selects the  $k$  smallest eigenvalues of graph Laplacian matrix ( $L$ ) and corresponding eigenvectors ( $u_1, \dots, u_k$ ), and applies K-means on rows of the spectral embedding matrix  $U$  composed from the eigenvectors as its columns.
- **Theoretical guarantees** of the effectiveness of vertex projection into a lower-dimensional spectral domain.

⇒ **Extension to Multi-layer Graphs using a common spectrum of the Laplacian matrices of the different layers.**

# Current Section

## 1 Context

- Multi-Layer Graphs
- Spectral Clustering

## 2 Methodology

- Clustering with Generalized Eigen-Decomposition
- Clustering with Spectral Regularization

## 3 Experiments

- Experiments : Results

## 4 Limitations and Extensions

- Sensitivity to Layer Importance Order
- Modularity Analysis
- Scalability
- Reproducibility

## 5 Conclusion

# Methodology: Clustering with Generalized Eigen-Decomposition

- **Core Idea:**

- **Aggregate** information from multiple layers : Find matrix  $P$  such that  $L_{\text{rw}}^{(i)} \approx P \Lambda^{(i)} P^{-1}$  for all  $i$ .
- Prioritize information from the most relevant layer for clustering.
- Compensation for sparse layers through the integration of information from remaining layers through **optimization**.

- **Optimization Problem:**

$$\min_{P, Q} \frac{1}{2} \sum_{i=1}^M \|L_{\text{rw}}^{(i)} - P \Lambda^{(i)} Q\|_F^2 + \frac{\alpha}{2} (\|P\|_F^2 + \|Q\|_F^2) + \frac{\beta}{2} \|PQ - I_n\|_F^2$$

# Methodology: Clustering with Spectral Regularization (1/2)

- **Core Idea:** Map the graph into 1-dimensional space such that projections of connected vertices are preserved as close as possible.
- Find a **smoothing** function  $f : V \rightarrow \mathbb{R}$  that preserves the proximity between the vertices for each layer:

$$\arg \min_f f^T L f \text{ s.t. } \|f\| = 1, f \perp 1$$

- If the eigenvalues are small, the eigenvectors of  $L$  are **good candidates**.

# Methodology: Clustering with Spectral Regularization (2/2)

- **For 2 layers:** we consider the first layer as **the most informative** and we compute the eigenvectors of  $L_{rw}^{(0)}$  denoted  $(u_1, \dots, u_k)$

$$\text{The smooth spectrum: } \arg \min_f \underbrace{\frac{1}{2} \|f_i - u_i\|^2}_{f_i \text{ close to } u_i} + \underbrace{\lambda f_i^T L_{rw}^{(1)} f_i}_{f \text{ smooth to the next layer}}$$

- **For m layers:** we can repeat the process by considering the current combination and the next informative layer.

⇒ The final function is the **join spectrum** for the clustering.

- Scalability
- Reproducibility

## 5 Conclusion

# Experiments: Datasets

## Cora[3]

- Extensive bibliographic repository with diverse research papers.
- Selected 900 papers within three ground truth clusters.

Figure 2: Spy plots of the adjacency matrices for the layers of the CORA dataset.

## MIT Reality Mining [4]

- Social network of 94 mobile users on the MIT campus.
- After preprocessing, narrowed down to 90 subjects organized into 7 clusters.

Figure 3: Spy plots of the adjacency matrices for the layers of the MIT dataset.

## AUCS[5]

- Extension to the original work with relationships among 61 university employees.
- Each subject is affiliated with one of 8 research groups, designated as the ground truth cluster.

Figure 4: Spy plots of the adjacency matrices for the layers of the Aucs dataset.

- **Implementation** of Spectral Clustering method for single-layer graphs, Generalized Eigen-Decomposition (**SC-GED**), and Spectral Regularization (**SC-SR**).
- **Baseline methods** : Kernel K-means (**K-Kmeans**) algorithm, the Spectral Clustering applied to **Single Layers**, the averaged Laplacian matrix algorithm (**SC-AL**), and the summation of adjacency matrices (**SC-SUM**)
- **Evaluation** of the performance using the **Purity**, the Normalized Mutual Information (**NMI**), and Rand Index (**RI**).

## 5 Conclusion

# Sensitivity to Layer Importance Order: SC-SR

How to properly sort layers according to their importance?

- Ideally, rely on **knowledge of expertise**
- **Exhaustive** search along all different permutations ( $d!$  complexity)
- Selection criteria evaluated **for each layer**

**Figure 5:** Influence of Informative Layer Order on SC-SR Method Performance evaluated on AUCS Dataset

# Modularity Analysis

- **Modularity:** Measures the quality of a partition. Higher modularity indicates more cohesive clusters, making a layer more meaningful for clustering.
- Evaluate layer ranking from most to least informative.
- AUCS dataset layer analysis shows Co-author and Lunch with the highest modularity.

Table 1: Modularity of Layers Based on Clustering Results

Lunch	Facebook	Leisure	Work	Coauthor
0.599	0.272	0.474	0.400	0.662

- **Limitations:**

- SC-GED method complexity:  $O(mn^3)$ .
- Complexity arises from eigen-decomposition and matrix inversions.

- **Application:**

- Applicable to small networks (approximately 100 nodes, 3 to 5 layers).
- Impractical and non scalable for real-life datasets are larger and more complex.

- **Challenges:**

- **Non-existence** of the preprocessing details for Cora and MIT datasets.
- Unclear criteria for paper selection in Cora and node/cluster selection in MIT.

⇒ Variability in results due to different data engineering strategies for adjacency matrix extraction.

- **Solutions:**

- Introduced a new dataset, AUCS, for reproducibility.
- Carefully constructed adjacency matrices.
- Precise ground truth labels for benchmarking.

# Current Section

## 1 Context

- Multi-Layer Graphs
- Spectral Clustering

## 2 Methodology

- Clustering with Generalized Eigen-Decomposition
- Clustering with Spectral Regularization

## 3 Experiments

- Datasets
- Algorithms and Evaluation Metrics
- Experiments : Results

## 4 Limitations and Extensions

- Sensitivity to Layer Importance Order
- Modularity Analysis
- Scalability
- Reproducibility

## 5 Conclusion

- Re-implemented two spectral-based multi-layer graph clustering methods: **SC-GED** and **SC-SR**.
- Extended the evaluation on a new **well-constructed** dataset.
- Demonstrated a slight **improvement** over existing methods and **competition** with certain baselines.
- Emphasized the **critical** impact of the order of informative layers.
- Encountered challenges such as **hyperparameter sensitivity**, requiring expert domain knowledge, and facing computational intensity issues with **limited scalability**.
